**CHENNAI**

**MADRAS MEDICAL COLLEGE**  
**CHENNAI-600 003.**

**MARCH 2007**

## **CERTIFICATE**

*This is to certify that dissertation entitled “**RADIOLOGICAL EVALUATION OF PRIMARY BRAIN TUMOURS USING COMPUTED TOMOGRAPHY AND MAGNETIC RESONANCE IMAGING**” submitted by **Dr. C. NELLAIAPPAN** appearing for MD (Branch - VIII) Radio Diagnosis Examination in March 2007 is a bonafide work done by him under my direct guidance and supervision in partial fulfillment of regulations of the Tamilnadu Dr.MGR medical university, Chennai. I forward this to the Tamilnadu Dr.MGR Medical University Chennai, Tamil Nadu, India.*

*Signature of the Guide & HOD*

**Prof.V.CHANDRASEKHAR MDRD,DMRD**

Head of the department,

Barnard Institute of Radiology

Madras Medical College

Chennai-600 003.

*Signature of the Director*

**Prof. T.S. SWAMINATHAN MD,DMRD**

Director

Barnard Institute of Radiology

Chennai-600 003.

**DEAN**

Madras Medical College,

Govt. General Hospital,

Chennai- 600 003.

## **DECLARATION**

I declare that this dissertation titled “**RADIOLOGICAL EVALUATION OF PRIMARY BRAIN TUMOURS USING COMPUTED TOMOGRAPHY AND MAGNETIC RESONANCE IMAGING**” has been conducted by me under the guidance and supervision of Dr.V.Chandrasekhar MD,DMRD, Head of Department, Barnard Institute Of Radiology, Madras Medical College, Chennai.

It is submitted in part of fulfillment of the requirement of award of MD (Branch - VIII) Radio Diagnosis – March 2007 to be held under the Tamil Nadu Dr.M.G.R. Medical University, Chennai. This has not been submitted previously by me for award of any Diploma or Degree in any other University.

**Dr. C. Nellaiappan**  
Postgraduate M.D., Radio Diagnosis  
Barnard Institute of Radiology,  
Madras Medical College,  
Chennai- 600 003.

## *Acknowledgement*

I express my sincere gratitude to **Prof.KALAVATHY PONNIRAIVAN, M.D., DEAN.**, Madras Medical College for giving me permission to conduct the study in this institution.

With extreme gratefulness, I express my indebtedness to **Prof.T.S.SWAMINATHAN, MDRD, DMRD, FICR**, Director, Barnard Institute of Radiology, for having encouraged me to take up this study .But for his guiding spirit, perseverance and wisdom, this study would not have materialized.

I express my sincere thanks and gratitude to my guide **Prof. V.CHANDRASEKAR, MDRD, DMRD**, Head of the Department, Barnard Institute of Radiology, for his immense kindness, constant support and consistent encouragement in conducting this study.

I wish to thank **Prof.KUPPUSWAMY, MDRD, DMRD, Prof.N.KULASEKARAN, MDRD, DMRD, Prof.C.ANNADURAI, MDRD,DMRD, Prof.K.VANITHA, MDRD, DMRD, DRM** for their support, valuable criticism and encouragement

I am greatly indebted to my Assistant professors **Dr. UMAPATHY, DMRD, Dr.SUNDARESWARAN, DMRD, Dr.NESAM MANIVANNAN DMRD, Dr.R.RAVI, MDRD, Dr.BABU PETER MDRD, Dr.RAMESH MDRD and Dr.C.AMARNATH, MDRD** for their untiring help.

I thank my fellow postgraduate colleagues for their help and co-operation during the study.

I thank all the staff of BARNARD INSTITUTE OF RADIOLOGY for helping me in conducting this study

I thank my parents and my wife for their support and encouragement. Finally I thank all my patients for their cooperation without whom this study would not have materialized.

## **INTRODUCTION**

Brain tumours are among the common neoplasms of humans. Patients tend to concentrate in institutions where diagnostic and the therapeutic services are available. The incidence of brain tumors is around 4 per 1,00,000 population. Supratentorial brain tumours constitute about 80% of brain tumours in adults and 40% of tumours in paediatric population. Brain neoplasms are found in 2% of autopsy series and account for 1% of all the hospital admissions<sup>1</sup>.

Diagnosis of brain tumours may be delayed as the initial symptoms and signs are vague and nonspecific. The symptoms include headache, focal seizures and focal neurological deficit, with clinical examination revealing, raised intracranial tension or focal neurological deficit.

Therefore the clinicians rely heavily on imaging for an early and accurate diagnosis. Significant advance has been made during the last two decades in radiological diagnosis and characterization of brain neoplasms.

The goals of diagnostic imaging in the patient with suspected intracranial tumor include detection of the presence of a neoplasm, localization of the extent of the tumor (including definition of involvement of key structures and assessment of the presence and severity of secondary changes, e.g., edema, herniation, hemorrhage), and characterization of the nature of the process. This has been made possible by modern imaging

modalities like CT and MRI and refinements of previous technique such as angiography. In addition stereotactic biopsy under imaging guidance permits histological diagnosis of brain neoplasm<sup>2</sup>.

Both CT and MRI provide excellent anatomic details and information regarding the presence, location and extent of brain tumours.

### **COMPUTED TOMOGRAPHY:**

CT has the capacity to differentiate a wide range of tissue types including air, fat, soft tissue and bone with superior spatial resolution. The use of iodinated contrast agents allow better delineation of vascular anatomy and pathological entities, and can differentiate enhancing lesion from surrounding reactive change. CT is highly sensitive to calcification and blood within the brain parenchyma. CT is preferred for the uncooperative and unstable patients, because each axial image is obtained separately. Thus, motion artifact is minimized, particularly in later generation scanners which can perform individual scans in less than 2 seconds.

CT characterization provides a better insight to the nature of lesion and its effect on the adjacent structures. It also provides a road map for the neurosurgeon regarding the approach, likely duration of surgery, requirements for anaesthesia etc.

Upgradation in recent CT technologies like helical mode helps in 3 dimensional visualization of the neoplasm.

Wider experience in CT and familiarity of the lesions in CT favor CT as an important and appropriate investigation tool.

#### **MAGNETIC RESONANCE IMAGING:**

MRI has rapidly earned recognition as the optimal screening technique for the detection of most intracranial neoplasms. Compared with CT, MRI using spin echo, gradient echo, and combination spin and gradient echo pulsing sequences before and after intravenous (IV) administration of paramagnetic contrast agents provides inherently greater contrast resolution between structural abnormalities and adjacent brain parenchyma and has proved to be even more sensitive in the detection of focal lesions of the brain. Early experience suggested that upto 30% more focal intracranial lesions could be identified on MRI than on CT<sup>3,4</sup>.

## **AIMS OF THE STUDY**

To assess the role of computed tomography, magnetic resonance imaging in

- 1) Detection & localization of primary brain tumours.
- 2) Characterisation of lesions, assessing extent and mass effect of lesions.
- 3) Giving specific diagnosis of the tumours using characteristics shown by CT and MRI.

## **REVIEW OF LITERATURE**

### **HISTORY:**

Within years after Wilhelm C. Roentgen announced the discovery of x-rays in 1895, Church reported the first use of x-rays to localize a brain tumour, a densely calcified cerebellar tumour. It soon became evident, however, that a non calcified lesion would be virtually indistinguishable by plain film alone.

The introduction of air ventriculography and pneumoencephalography by Walter Dandy in 1918 made it possible to deduce by indirect means the presence and size of intracranial masses by their compressive effect on the air filled ventricular system.

In 1927, Egas Moniz introduced cerebral angiography in which iodinated positive contrast was instilled into the intracranial arterial system; This allows for a more accurate diagnosis of intracranial masses by analysis of displacement of cerebral vessels.

For more than 50 years, pneumoencephalography and cerebral angiography were the only modalities for neuroradiological diagnosis of brain tumours.

With the advent of computer tomography in 1972 by Hounsfield, a British Physicist, cross sectional imaging techniques have since replaced these techniques for the evaluation of intracranial mass lesion. The original

EMI scanner was designed specifically for evaluation of the brain. In this unit the head was enclosed in a water bath between the x-ray to be above and a pair of detectors below.

One major objective of the later second and third generation scanners was to shorten the scanning time for each tomographic section.

Recently developed CT technology, spiral CT permits rapid volume data acquisition and reconstruction of the image in any plane. These techniques are faster than conventional CT and so there is less likelihood of motion artifacts.

The phenomenon of Magnetic resonance was described independently but almost simultaneously by Bloch and Purcell and their colleagues in 1946. Human in vivo images were first published in 1977 by Mansfield & Maudsley, Damadian et al and Hinshaw et al. Hawkes et al in 1980 demonstrated the multiplanar facility of MRI and reported the first demonstration of intra cranial pathology using MR.

## **DIAGNOSTIC IMAGING**

### ***Computed Tomography (CT)***

Before the introduction of computed tomography (CT) in the early 1970s, confirmation of the presence or absence of brain tumor involved the use of invasive diagnostic procedures (e.g., cerebral angiography or pneumoencephalography) that required hospitalization and carried some

morbidity and risk. Clinicians were often reluctant to submit patients with uncertain history and findings to such risks.

The advent of CT significantly altered the method and timing of diagnostic evaluation of the patient with suspected brain tumor.<sup>5, 6</sup> CT evaluation of the brain is relatively noninvasive and is therefore easily and rapidly accomplished. In the mid-1970s, CT emerged as the primary diagnostic screening modality for the detection of intracranial disease. Areas of structural abnormality (e.g., tumors) appeared on CT as regions of altered tissue radiographic density. Accuracy of localization with CT exceeded the accuracy that could be achieved by cerebral angiography or other invasive diagnostic procedures. Another important advantage of CT was the demonstration of no disease in the symptomatic patient who did not have a neoplasm or other structural abnormality, thus affording reassurance to the patient and physician and avoiding costly hospitalization and more invasive or more hazardous diagnostic procedures.<sup>7</sup> Conversely, CT occasionally revealed abnormalities (including tumors) that were not suspected clinically in patients with relatively nonspecific complaints.

### ***Magnetic Resonance Imaging (MRI)***

Lesions and tissues with increased water content appear even more conspicuous on T2-weighted MR images than on CT images obtained after IV infusion of contrast agents<sup>8</sup>. Delineation by MRI of normal and abnormal soft tissue anatomy in the posterior cranial fossa, near the base of the skull,

and in other areas of the brain that lie adjacent to dense bone is considerably better than with CT because of MRI's lack of the beam hardening artifacts secondary to absorption of x-rays in bone seen on CT. Accuracy of lesion localization on MRI is enhanced by its direct multiplanar capability, which permits acquisition of images in the coronal and sagittal plane in addition to the axial plane conventionally used in CT. MRI offers superior contrast resolution, including greater sensitivity for the detection of subacute and chronic hemorrhage in association with tumors and other structural lesions of the brain.

The ability with MRI (using conventional anatomic imaging protocols as well as MRI angiography sequences that display blood flow) to visualize vessels supplying and draining structural lesions in the brain adds yet another important dimension of information that can contribute to the diagnostic assessment.

Even with current state of the art equipment utilizing very high magnetic fields and rapidly switching gradient coils, MR nevertheless suffers two disadvantages in comparison with CT in the assessment of intracranial structural abnormalities. 1. MRI requires significantly longer acquisition times and 2. Abnormalities involving cortical bone, intratumoral calcification, and hyperacute hemorrhage are more clearly and accurately assessed with CT. Newer multi-slice helical or spiral CT scanners are capable of providing highly collimated submillimeter thickness sectional

images in extremely short acquisition times, and thus areas of hyperostosis or bone destruction, intratumoral calcifications, and early intratumoral or peritumoral hemorrhage are more completely defined with greater certainty on CT than on MRI. The much faster acquisition capability of current CT units strongly favors their use in patients who are critically ill or medically unstable. Also, in patients with magnetically controlled cardiac pacemakers and other internal paramagnetic metallic devices, the risk of the MRI magnet interacting with such devices may preclude the use of MRI.

Given both the higher cost and more restricted availability of MR equipment to date as well as continuing improvements in CT equipment and scanning techniques that permit shorter examination times with improved spatial and contrast resolution, it is not surprising that CT remains a major imaging technique for the follow up of intracranial mass lesions. In current clinical practice initial diagnosis and localization of brain lesions are most often accomplished with MRI, but the imaging modality of convenience for followup studies is often CT.

Multiplanar MRI also increases the diagnostic precision with which paraventricular masses can be differentiated from intraventricular masses. Paraventricular tumour characteristic all displace the choroid plexus and compress the lateral ventricles, whereas intraventricular masses cause local ventricular expansion and, generally conform to the shape of the ventricle.

Imaging (usually magnetic resonance imaging (MRI) is extensively utilized in treatment planning before surgery or radiation to define the gross tumour margins and to permit selection of the safest approach to the lesion.

Functional MRI is increasingly employed preoperatively to determine the location of functionally eloquent cortex, which can then be avoided during an operative approach. Interactive computerized neuronavigational devices utilize these data (1) to allow administration of very high doses of precisely focused radiation to small (up to 3 cm) intracranial tumors while sparing the adjacent normal brain and (2) to accurately register the previously acquired image data set onto intraoperative space, thus enabling precise intraoperative localization of surgical instrumentation relative to tumor margins, key vascular structures, and other critical anatomy. A relatively new and highly promising application is image guided surgery, in which the entire surgical resection is guided by direct real time MRI in the operating room environment.

Follow up assessment of intracranial neoplasms utilizes CT and MRI and related techniques extensively, including MRI spectroscopy and MRI perfusion weighted imaging, to monitor post-treatment complications and to detect the presence of residual or recurrent tumor.

## **NEWER DIAGNOSTIC TECHNIQUES:**

Accumulated experience together with continuing improvements in contrast discrimination and spatial resolution have permitted highly accurate correlation between CT and MRI appearance and histologic grading of supratentorial gliomas. However noninvasive differentiation between high grade glioma with a cystic or necrotic center, solitary metastatic carcinoma with central necrosis, resolving hematoma, resolving infarction, atypical mass like presentation of a tumefactive multiple sclerosis plaque, and cerebral abscess on the basis of CT or MRI findings remains a difficult task. Also, precise and accurate separation of infiltrating high grade glioma from surrounding edema is not currently attainable with either conventional MRI or CT, even after IV administration of contrast medium. Differentiation between recurrent tumor and radiation necrosis is another major diagnostic problem in the management of the patient with malignant glioma who has already undergone surgical resection with postoperative radiation therapy. Newer diagnostic techniques based on magnetic resonance are addressing these problems.

### ***Magnetic Resonance Spectroscopy (MRS)***

In magnetic resonance spectroscopy (MRS), the resonance signal that is utilized to generate an image in MRI is instead used to generate a frequency spectrum reflecting the components that make up that image<sup>9</sup>. In normal brain tissue, these components reflect both the water content of the brain and the metabolism of the normal neurons and glial cells. If the signal

from water is suppressed, the frequency spectrum (expressed in parts per million [ppm]) reflects the cellular metabolism of the brain in the voxel or section of tissue being interrogated.

The highest- peak amplitude in the normal brain frequency spectrum is that of N-acetyl aspartate (NAA), which occurs at a frequency of 2.0 ppm. NAA is a specific marker of neuronal density and viability. The next highest peak in the normal brain spectrum is that of creatine (Cr), at 3.03 ppm; creatine is involved in energy dependent processes of cellular metabolism in many different types of cells. The third highest peak of the normal brain spectrum is that of choline (Cho), which is involved in and reflects the metabolism of cellular membrane turnover; its frequency peak is 3.2 ppm. In normal brain, the ratio of the height of the choline peak to that of the creatine peak (Cho/Cr) is less than 1.0.

Another important metabolite peak occurs at approximately 1.32 ppm and reflects both lipids and lactate. Lactate is not a normal constituent of brain metabolism; its presence indicates that the normal cellular oxidative metabolism has been altered and that glycolysis is taking place via anaerobic pathways. An elevated lactate peak is seen in the presence of cellular necrosis and reflects lesions that have outgrown their blood supply- for example, the central portions of abscesses, malignant gliomas, lymphomas, and carcinomatous metastases. Lipids resonate at a similar frequency and are also found in highly malignant tumors.

When the interrogating voxel is placed on the peripheral contrast enhancing rim of a rounded intracerebral mass with central hypointensity on T1-weighted MRI, the MR spectroscopic pattern demonstrating elevation of the choline peak with depression of the NAA and creatine peaks is typical for both primary and secondary malignant tumors of the brain and does not aid in their differentiation. MRS of the central hypointense region of such a mass demonstrates elevated lactate and lipid signals, which indicate only the presence of necrosis and do not provide differential information. However, the choline peak in peripheral viable tissue is not elevated in inflammatory processes such as fungal, parasitic, and bacterial abscesses, possibly representing an important differential finding<sup>10</sup>.

It is clearly established that in malignant gliomas, infiltrating tumor cells are present well beyond, the contrast enhancing tumor margins seen on CT scans and MR images. However, in metastasis, the peritumoral region contains no infiltrating tumor cells. Studies involving MR spectroscopic interrogation of the peritumoral region in patients with solitary brain tumors have document elevated choline levels with reversal of the normal Cho/Cr ratio in the peritumoral region in patients who have infiltrating high grade gliomas but not in patients who have metastases<sup>11</sup>. This finding on MRS may enable the discrimination between malignant glioma and metastasis and suggests that the peritumoral hyperintensity on T2-weighted images and the peritumoral hypointensity on T1-weighted images seen in association with malignant gliomas may reflect not only

vasogenic edema but also tumor infiltration, whereas the lack of reversal of the normal Cho/Cr ratio in the peritumoral tissue surrounding metastases suggests that the similar MRI appearance of this tissue is likely due to edema or gliosis.

### ***PERFUSION-WEIGHTED MRI***

Another difference between patients with malignant glioma and those with metastasis has been noted on dynamic contrast enhanced perfusion-weighted MRI utilizing a first pass image acquisition protocol after bolus IV administration of gadolinium<sup>12</sup>. One Study has demonstrated a significant increase in relative cerebral volume (rCBV) in the peritumoral region in patients with malignant gliomas, and a diminished rCBV in the peritumoral region in patients with metastases. Increased peritumoral perfusion in patients with malignant gliomas is presumed to be due to tumor infiltration into the peritumoral region with associated loss of blood-brain barrier integrity. Diminished peritumoral perfusion in the tissue surrounding a metastasis may reflect an intact blood-brain barrier with the vasogenic edema causing local compression of the microcirculation.

### ***POSITRON EMISSION TOMOGRAPHY***

Studies of cerebral oxygen metabolism using the positron-emitting isotope fluorine- 18 tagged 2 fluoro deoxyglucose (FDG), an analogue of glucose, have established that most malignant brain tumors have increased glucose uptake and metabolism compared with normal brain parenchyma,

that the level of FDG uptake correlates well with histologic grade in cerebral gliomas, and that FDG positron emission tomography (PET) is a good predictor of prognosis in these tumors<sup>13</sup>.

Differentiation between recurrent tumor and radiation necrosis remains a major unsolved problem in the management of patients with malignant gliomas. Both processes can present the heterogeneous appearance of a growing infiltrative mass with irregularly margined contrast enhancement on CT and MRI. Early work suggested that necrotic tissue failed to take up the radioactivity and appeared hypometabolic and that actively growing tumor demonstrated strong hypermetabolic uptake. This finding was verified on a subsequent study demonstrating high sensitivity and specificity for FDG PET. However, other studies have questioned the accuracy and specificity, and therefore the utility, of FDG PET for this indication.

## **CLASSIFICATION OF PRIMARY BRAIN TUMOURS**

Bailey & Cushing in 1926 were the first to propose classifications of brain tumours based on the cell of origin, subsequently developed by Russel and Rubinstein in 1989, WHO subsequently devised a modification to Russel and Rubinstein classification in 1994 thus giving an impetus and standardization of Brain tumours. Neurons and neural glial cells are the two tissues that make up the central nervous system. Neuroglia consist of Astrocyte, Oligodendrocyte, microglia, ependyma and choroid epithelium.

Vast majority of brain tumours arise from the neuroglia and are included under a broad term gliomas. Added to the list of primary tumours are tumours arising from the pineal Body, meningiomas, germ cell tumours, and lymphoma. Dermoid, epidermoid, arachnoid cyst and colloid cyst are considered to be maldevelopmental in origin. Metastatic tumours represent secondary malignancies of the brain and its coverings.

The current International Histological classification of CNS tumours drafted in 2000 revision by the World Health Organisation is as follows<sup>14</sup>.

This classification has been adapted and modified from Kleihues P, Cavenee WK (eds): Pathology and genetics of the tumours of the nervous system. Lyon, international agency for research on cancer ,2000.

## **GLIAL TUMOURS**

### *Astrocytomas*

#### Circumscribed Astrocytomas

Juvenile Pilocytic Astrocytoma

Pleomorphic Xanthoastrocytoma

Subependymal giant cell astrocytoma

#### Diffuse Astrocytomas

Low grade astrocytomas

Optic pathway Glioma

Brain stem Glioma

Anaplastic Astrocytoma

Glioblastoma Multiforme

Gliomatosis Cerebri

Gliosarcoma

*Oligodendroglioma*

Low Grade Oligodendroglioma

Anaplastic Oligodendroglioma

*Ependymomas*

Ependymoma

Subependymoma

*Choroid plexus tumours*

Choroid plexus papilloma

Choroid plexus carcinoma

## **NONGLIAL TUMOURS**

*Neuronal and mixed*

*Neuronal / glial tumours*

Ganglioglioma

Gangliocytoma

Lehermitte – Duclos disease

Desmoplastic infantile ganglioglioma

Dysembryoplastic Neuro Epithelial Tumour

Central neurocytoma

*Pineal Parenchymal tumours*

Pineoblastoma

Pineocytoma

*Embryonal tumours*

Medulloblastoma

Supratentorial primitive neuroectodermal tumours

**TUMOURS OF THE CRANIAL NERVES**

Schwannoma

Neurofibroma

Malignant Peripheral nerve sheath tumours

**TUMOURS OF THE MENINGES**

Meningioma

Hemangiopericytoma

Mesenchymal non meningotheial tumours

Melanocytic tumours

Hemangioblastoma

**TUMOUR OF THE HEMOPOIETIC SYSTEM**

Primary CNS Lymphoma

Secondary CNS Lymphoma

Histiocytic lesions

Granulocytic sarcoma

## **GERMCELL TUMOURS**

Germinoma

Teratoma

Other germ cell tumours

## **TUMOURS OF THE SELLAR REGION**

Pituitary adenoma

Microadenoma

Macroadenoma

Craniopharyngioma

Rathke cleft cyst

Tumours Of The Neuro Hypophysis

Chordoma

## **METASTATIC TUMOURS**

Metastases to the brain

Metastases to the skull and intracranial dura

Leptomeningeal Metastasis (leptomeningeal carcinomatosis)

## **CHARACTERISTICS OF PRIMARY BRAIN TUMOURS**

### ***Location:***

Tumour location is important for differential diagnosis of brain neoplasms and for determining imaging technique. Coronal plane imaging of the sella is an example of adjusting imaging technique for tumour location<sup>15</sup>.

Extra axial location are typical of Benign intracranial neoplasm and parenchymal infiltration is characteristic of malignant brain tumours. On imaging extra axial masses buckles the white matter, expands the ipsilateral subarachnoid spaces, and sometimes causes reactive bone changes. An intraxial mass expands the cortex of the brain, separation of the lesion from the underlying leptomeninges is not seen, lesion spreads across well defined boundaries, and the dura is seen peripheral to the mass.

List of differential diagnosis of common supratentorial primary Brain tumours in relation to the anatomical location.

I. Cerebral Hemispheres

Astrocytoma

GBM

Oligodendroglioma

Meningioma

II. Leptomeninges & Dura

Meningioma

Metastasis

Lymphoma

Leukemia

III. Deep structure (periventricular, thalamus and basal ganglia)

Primary Cerebral lymphoma

Primary Cerebral neuroblastoma

Glioma – often High grade

- IV. Corpus Callosum
  - GBM
  - Lymphoma
  - Metastasis
  - Lipoma (in Corpus Callosal Agenesis)
  
- V. Lateral ventricle
  - Ependymoma
  - Meningioma
  - Choroid plexus Papilloma
  - Primary cerebral neuroblastoma
  - Subependymoma
  
- VI. Foramen of Monro
  - Giant cell astrocytoma
  - Colloid cyst
  - Ependymoma
  - Subependymoma
  
- VII. Third Ventricle
  - Colloid cyst
  - Ependymoma
  
- VIII. Optic chiasma region
  - Pilocytic astrocytoma
  - Craniopharyngioma
  - Meningioma
  - Germinoma
  - Arachnoid cyst

- IX. Pituitary region  
Adenoma  
Craniopharyngioma  
Meningioma  
Dermoid tumour  
Rathke Cleft cyst

- X. Pineal region  
Germinoma  
Teratoma  
Pineocytoma  
Glioma

## **INFRATENTORIAL LESIONS**

### *ADULT*

- Metastases  
Hemangioblastoma  
Acoustic schwannoma  
Meningioma  
Epidermoid  
Other schwannomas  
Vascular lesions  
Parangliomas

### *CHILDREN*

- Medulloblastoma  
Cerebellar astrocytoma  
Brainstem glioma  
Ependymoma and choroids plexus papilloma

## **MARGINS:**

Smooth, sharply defined margins favor the diagnosis of benign lesion, and irregular, poorly defined margins favor malignant neoplasms, due to their tendency for parenchymal infiltration.

## **PARENCHYMA:**

Heterogeneity in a tumour are due to Hemorrhage, calcification, fat, cyst formation and necrosis.

## **CT & MRI CHARACTERISTICS OF COMMON PRIMARY NEOPLASMS<sup>16</sup>**

### **1. DIFFUSE ASTROCYTOMA, LOW GRADE**

#### ***CT Findings***

##### **NECT**

- Illdefined homogeneous hypodense/isodense mass
- 20% Ca++; cysts are rare
- Calvarial erosion in cortical masses (rare)

##### **CECT**

- No enhancement or very minimal
- Enhancement should raise suspicion of focal malignant degeneration

#### ***MR findings***

- T1WI
  - Homogeneous hypointense mass
  - May expand white matter and adjacent cortex
  - Appears circumscribed, but infiltrates adjacent brain
  - Hemorrhage or surrounding edema (rare)

- T2WI
  - Homogeneous hyperintense mass
  - May appear circumscribed, but often infiltrates adjacent brain
- FLAIR: Homogeneous hyperintense mass
- DWI: Restricted diffusion usually absent
- T1 C+ :
  - Usually no enhancement
  - Enhancement suggests progression to higher grade
- MRS
  - High choline, low NAA typical but not specific

## **2. ANAPLASTIC ASTROCYTOMA**

### ***CT Findings***

#### **NECT**

- Low density ill-defined mass
- Ca++ and hemorrhage rare

#### **CECT**

- Majority do not enhance
- Enhancement often focal, patchy, heterogeneous

### ***MR findings***

- T1WI
  - Mixed isointense to hypointense WM mass
  - Ca++, hemorrhage, cysts rare

- T2WI
  - Heterogeneously hyperintense
  - May appear discrete, but infiltrates adjacent brain
  - May involve and expand overlying cortex
  - Ca++ , hemorrhage, cysts are rare
- FLAIR: Heterogeneously hyperintense
- DWI: No diffusion restriction is typical
- T1 C+ :
  - Usually no enhancement
  - Less common: focal, nodular, homogeneous, patchy enhancement

### 3. GLIOBLASTOMA MULTIFORME

#### ***CT Findings***

#### NECT

- Irregular isodense or hypodense mass with central hypodensity representing necrosis
- Marked mass effect and surrounding edema/tumour infiltration
- Hemorrhage not uncommon
- Ca++ rare (related to low grade tumor degeneration)

CECT: 95% have strong, heterogeneous, irregular rim-enhancement.

### **MR findings**

- T1WI
  - Irregular isointense, hypointense white matter mass
  - Necrosis, cysts and thick irregular margin common may have sub acute hemorrhage.

T2WI :

- Heterogeneous, hyperintense mass with adjacent tumor infiltration/ vasogenic edema.
- Viable tumor extends far beyond signal changes

Necrosis, cysts, hemorrhage, fluid/debris levels, flow voids (neovascularity) may be seen

- FLAIR: Heterogeneous, hyperintense mass

- DWI :
  - Lower measured ADC than low grade gliomas
- T1 C+ :
  - Thick, irregular ring of enhancement surrounding central necrosis typical
  - Enhancement may be solid, ring, nodular or patchy

## **4. PILOCYTIC ASTROCYTOMA**

### **CT Findings**

NECT

- Discrete cystic/solid mass
- May have little or no surrounding edema
- Ca++ , 20%, hemorrhage rare

## CECT

- >95% enhance (pattern vary)
- 50% nonenhancing cyst, strongly enhancing mural nodule.

## **MR findings**

- T1WI
  - Solid portion iso/hypointense to GM
  - Cyst contents iso-to slightly hyperintense to CSF
- T2WI
  - Solid portions hyperintense to GM
  - Cyst contents hyperintense to CSF
- FLAIR:
  - Solid portions hyperintense to GM
  - Cyst contents do not suppress: Hyperintense to CSF
- T1 C+:
  - Intense but heterogeneous enhancement of solid portion
  - Cyst wall occasionally enhances

## **5. PLEOMORPHIC XANTHOASTROCYTOMA**

### **CT Findings**

#### NECT

- Cystic/Solid mass: Hypodense with mixed density nodule
- Minimal or no edema is typical
- Ca++ , hemorrhage, frank skull erosion rare

CECT: Strong, sometimes heterogeneous enhancement of tumor nodule.

### ***MR findings***

- T1WI
  - Mass is hypointense or isointense to gray matter
  - Mixed signal intensity may be seen
  - Cystic portion isointense to CSF
- T2WI
  - Hyperintense or mixed signal intensity mass
  - Cystic portion isointense to CSF
- FLAIR: Hyperintense or mixed signal intensity mass
- Cystic portion isointense to CSF
- T1 C+ :
  - Enhancement usually moderate/strong, well-delineated
  - Enhancement of adjacent meninges, dural “tail” common approximately 70 %.
  - Enhancing nodule often abuts pial surface

## **6. SUBEPENDYMAL GIANT CELL ASTROCYTOMA**

### ***CT Findings***

#### **NECT**

- Hypodense → Isodense
- Ca++ variable
- Hydrocephalus

## CECT

- Heterogeneous, strong enhancement
- Initially tumor typically >1cm

## **MR findings**

- T1WI
  - Hypointense to isointense to GM
  - $\pm$ Ca++ (hyperintense to hypointense)
- T2WI
  - Heterogeneous
- FLAIR: Heterogeneous hyperintense
- Periventricular interstitial edema from ventricular obstruction

## **7. OLIGODENDROGLIOMA**

### **CT Findings**

## NECT

- Mixed density(hypodense/isodense) hemispheric mass that extends to cortex.
- Majority calcify, nodular or clumped Ca++ (70-90%)
- Cystic degeneration common (20%)

## CECT

- Approximately 50% enhance
- Enhancement varies from none to striking

### **MR findings**

- T1WI
  - Hemispheric mass, hypointense to isointense to GM
  - Typically heterogeneous
  - Cortical and subcortical with cortical expansion
- T2WI
  - Typically heterogeneous, hyperintense mass
  - Heterogeneity related to Ca++ , cystic change, blood products
- Typically expands overlying cortex
- FLAIR
  - Typically heterogeneous, hyperintense
- DWI: No diffusion restriction is typical
- T1 C+ :
  - Heterogeneous enhancement is typical

## **8. EPENDYMOMA**

### **CT Findings**

#### NECT

- Infratentorial
  - 4<sup>th</sup> ventricular tumour extends into CPA/Cisterna magna
  - Ca++ common (50%); +/- cysts, hemorrhage
- Supratentorial
  - Large heterogeneous periventricular mass
  - CA++ common (50%)

CECT: Variable heterogeneous enhancement

**MR findings**

- T1WI
  - Heterogeneous, usually iso-to hypointense
- T2WI
  - Heterogeneous, usually iso-to hyperintense
- FLAIR
  - Can show sharp interface between tumour and CSF
  - T1 C+: Mild to moderate, heterogeneous enhancement

**9. SUBEPENDYMOMA**

**CT Findings**

NECT

- Isodense to hypodense intraventricular mass
- Cysts or Ca++ may be seen in larger lesions.

CECT

- No enhancement, mild enhancement typical

**MR findings**

- T1WI
  - Intraventricular mass, hypointense or isointense to white matter
  - Typically homogeneous solid mass
- T2WI
  - Hyperintense intraventricular mass

- FLAIR: Hyperintense intraventricular mass
- T1 C+: Variable enhancement, typical none to mild

## 10. CHOROID PLEXUS PAPILLOMA

### ***CT Findings***

#### NECT

- Intraventricular bosselated mass
- 75% iso-or hyperattenuating
- Ca++ in 25%, hydrocephalus

#### CECT

- Intense, homogeneous enhancement
- Heterogeneous enhancement suggests choroid plexus carcinoma (CPCA)

### ***MR findings***

- T1WI
  - Well delineated, lobulated mass
  - Iso-to hypointense
- T2WI
  - Iso-to hyperintense
- FLAIR: Bright periventricular signal
- T1 C+ : Robust homogeneous enhancement
- MRA: Flow related signal within mass
- Enlarged choroidal artery (trigonal mass)

## 11. DYSEMBRYOPLASTIC NEURO EPITHELIAL TUMOUR-DNET

### ***CT Findings***

#### NECT

- Wedge-shaped low density area
- Cortical / subcortical lesion
- Scaloped inner table in 44-60%.

#### CECT

- Usually nonenhancing

### ***MR findings***

- T1WI
  - Pseudocystic, multinodular (“bubbly”) mass
  - Hypointense on T1
- T2WI
  - Very hyperintense on T2
- FLAIR: Mixed (hypo/isointense) signal with “bright” rim.
- DWI: Usually lacks restricted diffusion
- T1 C+: Usually does not enhance

## 12. CENTRAL NEUROCYTOMA

### ***CT Findings***

#### NECT

- Usually mixed solid and cystic (Isodense/hyperdense)
- Ca++ common, 50-70%
- Hydrocephalus common

CECT:            Moderate, heterogeneous enhancement

***MR findings***

- T1WI
  - Heterogeneous, mostly isointense to gray matter cysts are hypointense.
- T2WI
  - Heterogeneous, hyperintense “bubbly” appearance
- FLAIR:    Heterogenous, predominantly hyperintense mass
- T1 C+:    Moderate to strong heterogeneous enhancement

**13. PINEOBLASTOMA**

***Imaging Findings***

- Large, heterogeneous pineal mass with “exploded”, peripheral Ca++
- Nearly 100% with obstructive hydrocephalus

**14. PINEOCYTOMA**

***Imaging Findings***

- Enhancing, circumscribed pineal mass which “explodes” pineal ca++
- May mimic pineal cyst or pineoblastoma

## **15. MEDULLOBLASTOMA (PNET-MB)**

### ***CT Findings***

#### **NECT**

- Solid mass in 4<sup>th</sup> ventricle
- 90% hyperdense
- Ca++ in upto 20%; hemorrhage rare
- Hydrocephalus common (95%)

#### **CECT**

- >90% enhance
- Relatively homogeneous

### ***MR Findings***

- T1WI: Hypointense to gray matter (GM)
- T2WI: Near GM intensity
- Flair: Hyperintense to brain
- DWI: Restricted diffusion +
- T1 C+
  - >90% enhance
  - Often heterogeneous

## **16. SCHWANNOMA**

### ***CT Findings***

#### **NECT**

- Cranial nerve schwannoma
- Noncalcified extra-axial mass
- Iso/slightly hyperdense compared to brain
- May enlarge bony foramina (IAC, foramen ovale, facial nerve canal)

CECT: Strong, uniform enhancement

**MR Findings**

- T1W1: Usually iso-, sometimes mixed iso-/hypointense
- T2WI: Hyperintense (nodule may be isointense)
- DWI: Solid portion of schwannomas shows no restriction
- T1 C+
  - Enhances strongly
  - Cranial nerve schwannoma: 2/3 solid; 2/3 ring or inhomogeneous.

**17. PITUITARY MACROADENOMA**

**CT Findings**

NECT

- Variable attenuation
- Typical - usually isodense with gray matter GM
- Cyst formation , necrosis common
- Hemorrhage 10% ;  $\text{Ca}^{++}$  1-2%
- Large Adenomas expand sella, may erode floor
- Aggressive adenomas extend inferiorly invade sphenoid,
- May destroy upper clivus

CECT : Moderate , some what inhomogenous enhancement

**MR Findings**

T1WI :

- Usually isointense with GM
- subacute hemorrhage has short T1

- Fluid-fluid levels may occur especially with pituitary apoplexy
- PPBS absent in 20 % of large adenomas
- Cavernous sinus invasion difficult to determine (medial wall is thin, weak )

T2WI:

- Most common - isointense with gray matter
- Less common
  - Cysts – hyperintense, hemorrhage
  - Dense granulated GH producing adenomas are often hypointense
  - Uncommon – High signal along optic tracts
  - FLAIR :Hyper intense to brain gray matter
  - T1 C+ : Enhances well
  - MRA : ICA s often displaced, encased rarely occluded.

## **18. CRANIO PHARYNGIOMA:**

### ***CT Findings***

NECT

- Adamantinomatous type 90%, mixed solid (iso), cystic (hypodense)
- 90% calcify

CECT: 90 % ENHANCE

### ***MR Findings***

- T1 WI :
  - Adamantinous type - hyperintense
  - Papillary type - isointense

- T2WI :
  - Cyst – hyper intense
  - Solid – Hetero intense
- FLAIR : Cyst- Hyperintense
- DWI : Variable
- T1C+: Cyst walls Enhance , solid portions – Heterogenous Enhancement

## **19. MENINGIOMAS:**

### ***CT Findings***

NECT:

- Hyperdense 75 %
- Calcification 20% - 25%
- Necrosis rare
- Hyper ostosis and irregular cortex +

CECT :

- More than 90% Enhance homogenously and intensely

### ***MR Findings***

- T1 WI : Iso to hypo with GM
- T2WI : Variable
  - Best to visualize CSF cleft
- DWI : Variable
- T1 C+: More than 95% Enhance homogenously and intensely
- Dural tail 35%- 80% of the cases(non specific)

## **20. ARACHNOID CYST:**

### ***CT Findings***

NECT: CSF density

CECT : No enhancement

### ***MR Findings***

- T1 WI : Isointense to CSF
- T2 WI : Isointense To CSF
- FLAIR : Suppresses completely
- DWI : No restriction
- T1C+ : No enhancement

## **21. EPIDERMOID CYST :**

### ***CT Findings***

NECT:

- CSF density
- 10%-25% Calcification +

CECT: May show cyst margin enhancement

### ***MR Findings***

- T1WI : Slightly hyperintense to CSF
- T2 WI : Iso intense To CSF
- FLAIR : Not Suppressed completely
- DWI : Restricted diffusion +
- T1C+ : May show cyst margin enhancement (35%)

## 22. BRAIN STEM GLIOMA:

- Classic Imaging appearance varies with tumour type and location
- TECTAL: Pilocytic, focal, variable enhancement, ca++
- FOCAL TEGMENTAL MESENCEPHALIC: Pilocytic, cyst + nodule
- DIFFUSE PONTINE GLIOMA: Fibrillary, diffuse, non enhancing.

### ***Incidence:***

Incidence of intracranial tumours in Indian series by Dr.B.Ramamurthy 1978 to 1994<sup>17</sup>.

<b>S.NO</b>	<b>TUMOURS</b>	<b>PERCENTAGE</b>
1	Gliomas	42.09%
2	Meningiomas	15.09%
3	Pituitary tumours	15.15%
4	Schwannoma	8.99%
5	Metastasis	6.21%
6	Vasoformative tumours	3.37%
7	Developmental tumours	6.42%
8	Lymphoreticulosis	0.58%
9	Skull tumours	0.32%
10	Sarcomas	0.85%

## **MATERIALS AND METHODS**

The study comprised of 80 patients including 41 males and 39 females age ranging from 1 year to 65 years. The study was conducted for a period of 18 months from March 2005 to august 2006.

The patients were referred from Institute of Neurology, Government General Hospital, Chennai, Institute of Child Health, Egmore, Chennai-8 to Barnard Institute of Radiology for radiological evaluation.

Clinically the most frequent symptom was head ache. Predominant clinical features were seizure, focal neurological deficit, cranial nerve palsies and loss of consciousness.

### ***Inclusion Criteria:***

All the patients who had radiological features suggestive of primary brain tumour.

### ***Exclusion Criteria:***

- 1) Patients who had already been worked up elsewhere and referred here with tissue diagnosis.
- 2) Patients with known primary tumor elsewhere in the body with features of metastases to brain.
- 3) Patients who were contraindicated for magnetic resonance imaging (Pace Makers, Claustrophobia).

## **COMPUTED TOMOGRAPHY:**

CT was done with TOSHIBA X SPEED Third Generation Scanner  
Machine Parameters:

Tube Voltage : 120 kv

Tube Current : 80 mA

Scanning time : 4 sec

Filter : FC 20

## **TECHNIQUE OF THE STUDY:**

Axial study was performed in all the cases and coronal study was performed in relevant cases especially tumours of sella.

### ***Axial study done with following parameters:***

Patient position: Supine with closed Eyes

Slice Thickness : 10 mm

Slice Interval : 10 mm (for supratentorial)

5mm (for infra tentorial)

Plane of Section: Osteo-Meatal Line

Extent of Study: From Base of the Skull to the High parietal region

### ***Protocol For Coronal study:***

Patient position: Prone with extended neck and closed Eyes

Slice Thickness : 5 mm

Slice Interval : 5 mm

Plane of Section: Perpendicular to the Hard palate

Extent Of Study: In the region of interest

2mm thin sections were carried out in both axial and coronal studies in the region of interest for better spatial resolution.

Contrast Study was performed in all cases and injected as rapid bolus. Quantity of the contrast media: 60 ml of Iohexol in rapid bolus.

## **MRI TECHNIQUES**

MRI was performed using 1.5 Tesla superconducting SIEMENS MAGNETOM, symphony using head coil.

POSITION: Patient is placed in supine position in the MRI gantry with head coil positioned.

## **MRI TECHNIQUES USED:**

Multiplanar scout sections were obtained for planning sequences. Imaging of whole brain MR from vertex to foramen magnum including base of skull using axial, coronal and sagittal sections with the following sequences was done.

### ***T1WI***

TR: 500 msec      S/G – 5 / 1.5  
TE: 14 msec

### ***FLAIR***

TR: 9000 msec      S/G – 5 / 1.5  
TE: 105msec

### ***T2WI***

TR: 4000 msec      S/G – 5 / 1.5  
TE: 93msec

### ***DWI***

TR: 4300 msec      S/G – 5 / 1.5  
TE: 123msec  
b : 0,500,1000

**MRA 3D TOF**

TR: 839 msec      S/G – 5 / 1.5

TE: 6.8 msec

**MRV 2D T0F**

TR: 30 msec S/G – 5 / 1.5

TE : 6.5 msec

**GRE T2 Axial**

TR: 839 msec      S/G – 5 / 1.5

TE: 27msec

**Contrast study**

It was performed in all cases – axial, sagittal, coronal sections using T1WI were taken.

*Quantity of contrast:* 0.1 mmol/kg of dimeglumine Gadopentitate.

For interpretation the following aspects of brain tumours were studied and analysed in these patients.

1.    **Location**
2.    **Margins**
  - Ill defined margins
  - Moderately defined margins
  - Well defined margins
3.    **CT Characteristics**
  - Density
  - Calcification
  - Hemorrhage

- Mass effect
- Contrast enhancement

#### 4. **MRI Characteristics**

- T1 Signal intensity
- T2 Signal intensity
- FLAIR
- Diffusion
- Mass Effect
- Contrast Enhancement

The contribution of CT and MR towards the above mentioned aspects were analysed for arriving the radiological diagnosis.

Tissue biopsy and surgical exploration with tissue diagnosis were considered to confirm the diagnosis.

## RESULTS AND ANALYSIS

**TABLE – 1:  
DISTRIBUTION OF PRIMARY BRAIN TUMOURS**

S.NO	TUMOURS	NO OF CASES
1	Gliomas	42
2	Meningiomas	11
3	Sellar & Supra Sellar lesions	7
4	Medulloblastoma	7
5	Schwannoma	5
6	Arachnoid cyst	2
7	Epidermoid cyst	2
8	Intraventricular tumours	4

**TABLE – 2**  
**SEX DISTRIBUTION**

<b>S.NO</b>	<b>TUMOURS</b>	<b>No of cases</b>	<b>sex</b>			
			<b>Male</b>	<b>%</b>	<b>Female</b>	<b>%</b>
1	Gliomas	42	25	59.5	17	40.5
2	Meningiomas	11	3	27.2	8	72.8
3	Sellar & Supra Sellar lesions	7	4	57.1	3	42.9
4	Medulloblastoma	7	4	57.1	3	42.9
5	Schwannoma	5	2	40	3	60
6	Arachnoid cyst	2	0	0	2	100
7	Epidermoid cyst	2	1	50	1	50
8	Intraventricular tumours	4	2	50	2	50

**TABLE - 3**  
**AGE DISTRIBUTION**

<i>Age</i>	<i>Glioma</i>	<i>Menin- gioma</i>	<i>SELLAR</i>	<i>Medullo Blastoma</i>	<i>Schwa- nnoma</i>	<i>Arach cyst</i>	<i>Epiderm cyst</i>	<i>Intra ventricular</i>
0-10	1	–	3	3	–	2	–	1
11-20	5	–	1	4	1	–	–	1
21-30	5	2	3	–	–	–	–	2
31-40	7	1	–	–	3	–	1	–
41-50	13	4	–	–	–	–	1	–
51-60	8	3	–	–	1	–	–	–
61-70	3	1	–	–	–	–	–	–

**TABLE -4**  
**~~DISTRIBUTION OF SUB TYPES OF GLIOMAS~~**

<b>S.No</b>	<b>SUB TYPES</b>	<b>No of cases</b>	<b>PERCENTAGE</b>
1	Low grade astrocytoma	8	19.5%
2	Anaplastic astrocytoma	11	26.6%
3	Glioblastoma Multiforme	17	40.9%
4	Circumscribed Astrocytomas	4	9%
5	Oligodendroglioma	2	4%

Out of 42 patients of gliomas, 17 patients (40.9%) were GBM, 11 patients (26.6%) were anaplastic astrocytoma.

**TABLE – 5**  
**DISTRIBUTION OF PRIMARY BRAIN TUMOURS BY LOCATION**

	<b><i>Distribution</i></b>	No of cases	Percentage
1.	Supratentorial	59	73.7%
2.	Infratentorial	21	26.3%
	<b><i>Total</i></b>	80	-

Most of the primary brain tumours are located supratentorially.

**TABLE – 6**

		<b><i>Intraaxial</i></b>	<b><i>%</i></b>	<b><i>Extra axial</i></b>	<b><i>%</i></b>	<b><i>Total</i></b>
1.	Supratentorial	37	62.7%	22	37.3%	59
2.	Infratentorial	12	57.1%	9	42.9%	21

Infratentorially the occurrence of extra axial lesion are more common than supra tentorial location(table 5).

**TABLE - 7**  
**INTRAVENTRICULAR TUMOURS**

Site	No of cases	%
Body of the lateral ventricles	2	50%
Atrium	1	25%
Foramen of Monro	1	25%

Lateral ventricular tumours were the commonest location for intra ventricular tumours.

**TABLE - 8**

S.No	Tumour	Total Cases	Calcification		Hemorrhage	
			No of cases	%	No of cases	%
1	Glioma	42	5	11.9%	9	21.4%
2	Meningioma	11	3	27.2%	0	-
3	Sellar	7	3	42.8%	0	-
4	Medulloblastoma	7	2	28.5%	0	-
5	Schwannoma	5	0	-	0	-
6	Arachnoid Cyst	2	0	-	0	-
7	Epidermoid cyst	2	0	-	0	-
8	Intraventricular tumours	4	1	25%	0	-

Calcification was noted in 14 cases, out of 80 cases of primary brain tumours.

In glioma of 42 cases only 5 (11.9%) showed calcification. In meningiomas of 11 cases ,3 (27.2%) showed calcification. All 3 cases of craniopharyngioma showed calcification.

Hemorrhage was seen in 9 cases all were proved to be glioblastoma in HPE.

**TABLE – 9**  
**MRI SIGNAL CHARACTERISTICS OF TUMOURS**

SEQUENCE	HYPO	HYPER	ISO	HET
T1 WI	51	1	4	24
T2 WI	3	37	7	33

Most tumours were hypointense on T1WI and hyperintense on T2 WI.

**TABLE - 10**  
**CONTRAST ENHANCEMENT OF THE GLIOMAS**

GLIOMAS	TOTAL	NO CE		ENHANCEMENT			
		No of cases	%	MILD CE	MOD CE	INTENSE	%
LA	8	8	100%	-	-	-	-
AA	11	6	54.5%	3	2	-	45.5%
GBM	17	-	-	-	8	9	100%
CIRC A	4	-	-	2	2	0	100%
ODG	2	-	-	2	-	-	100%

Low grade astrocytoma- No enhancement noted

Mild to moderate enhancement noted in 5 cases(45.5%) of AA.

Moderate to intense enhancement noted in 17 cases (100%) of GBM.

**TABLE – 11**  
**MENINGIOMA IN T2WI SEQUENCES**

T2	NO OF CASES	PERCENTAGE
ISO	6	55%
HYPO	1	9%
HYPER	2	18%
HET	2	18%

64% of meningiomas were iso to hypointense on T2WI. two cases were hyperintense on T2WI which were histologically turned out to be meningothelial type.

**TABLE - 12**  
**DIFFUSION RESTRICTION OF TUMOURS**

TUMOURS	TOTAL NO OF CASES	NO RESTRICTION		RESTRICTION	
		CASES	%	CASES	%
GLIOMA	42	42	100%	-	-
MENINGIOMA	11	11	100%	-	-
SELLAR LESIONS	7	7	100%	-	-
MEDULLOBLATOMA	7	4	57%	3	43%
SCHWANNOMA	5	5	100%	-	-
ARACHNOID CYST	2	2	100%	-	-
EPIDERMOID CYST	2	0	-	2	100%
INTRAVENTRICULAR TUMOURS	4	4	100%	-	-

Diffusion restriction noted in epidermoid cysts 100% , medulloblastomas 42.8%.

## **DISCUSSION**

In our study of 80 patients, 52.5% were gliomas. Out of 42 cases of gliomas, 17 cases were glioblastoma multiforme, 11 anaplastic astrocytoma, 8 low grade astrocytoma, 4 circumscribed astrocytoma, 2 were oligodendroglioma. The peak incidence of these tumours were 5<sup>th</sup> and 6<sup>th</sup> decade and male to female ratio is 1.47:1.

The incidence, peak age of presentation are comparable to De Jongh et al., 1978 and Silverman et al in 1981<sup>18</sup>.

In our study of 17 cases of glioblastoma multiforme, all were heterointense on T1WI due to hemorrhage and necrosis. CT and MRI diagnosis was made in 15 cases of glioblastoma multiforme and other two appeared as anaplastic astrocytoma which were glioblastoma multiforme on HPE.

Of 11 cases of anaplastic astrocytoma, 1 case radiologically appeared as glioblastoma multiforme.

On contrast administration, no enhancement was noted in low grade astrocytomas. Enhancement was noted in 45.5% of anaplastic astrocytoma, 100% of glioblastoma multiforme. There is relationship of contrast enhancement and tumour grading noted in our study. All glioblastoma

multiforme cases showed intense enhancement of tumour margins (non necrotic areas).

This is comparable to the results of Earnest F IV, Scheithauer BW et al., in year 2000, in which the intensity of the enhancement is significant and correlates with the level of cellular anaplasia<sup>19</sup>.

Hemorrhage was noted in 9 cases of 42 gliomas and all were glioblastoma multiforme.

So grading of malignancy using CT and MRI is 92%. Study of Dean B, Drayer B, Bird C et al in 1990 showed that the imaging features on CT & MRI, although generally correlating with tumour grade, are not entirely specific<sup>20</sup>.

Calcification was noted in 14 cases out of 80 cases of primary brain tumours. In glioma of 42 cases only 5 (11.9%) showed calcification. In meningiomas of 11 cases, 3 (27.2%) showed calcification. All 3 cases of craniopharyngioma showed calcification.

Dense calcification noted in oligodendroglioma, mural nodule calcification was noted in pilocytic astrocytoma.

In three cases of craniopharyngioma all showed calcification in the solid component. One of two cases of central neurocytoma showed calcification.

### **LOW GRADE ASTROCYTOMA:**

Incidence of low grade astrocytoma in our study was 10% of primary brain tumours.

Most cases displayed no mass effect, no calcification, no hemorrhage. No contrast enhancement noted.

Smirniotopoulos JG et al in 1999 showed that in low grade astrocytoma the contrast enhancement is usually absent reflecting a lack of tumour vascularity, blood brain barrier break down, or both. The above character is also noted in our study<sup>21</sup>.

All lesions appeared hypointense on T1, most appeared hyperintense on T2 and showed no diffusion restriction. There was one false negative case in which radiologically appeared granulomatous lesion turned out to be low grade astrocytoma on HPE. Hence the sensitivity is 87.5% in diagnosing low grade astrocytoma by CT & MRI.

### **ANAPLASTIC ASTROCYTOMA:**

Incidence of anaplastic astrocytoma in our study was 13.7% of primary brain tumours.

Peak age of incidence –4<sup>th</sup> and 5<sup>th</sup> decade.

Male: female ratio 1.2:1.

In our study anaplastic astrocytomas were ill defined, exhibited moderate mass effect.

Contrast enhancement noted in 5 cases. Calcification and hemorrhage were not seen. In MRI most lesion appear hetero intense on T2 WI. Out of 11 cases of anaplastic astrocytoma, 10 cases identified as anaplastic astrocytoma radiologically and one case reported as glioblastoma multiforme. Hence the sensitivity of CT & MRI in diagnosing AA is 90.9%.

### **GLIOBLASTOMA MULTIFORME:**

Incidence of glioblastoma multiforme in our study was 21.2% of primary brain tumours.

Male: female ratio 1.4:1.

Peak age of incidence –5<sup>th</sup> and 6<sup>th</sup> decade

All the glioblastoma multiforme were ill defined in CT, exhibited more mass effect and heterogeneity and more vasogenic oedema. All showed areas of necrosis and hemorrhage which were clearly demonstrated on MRI. Calcification was noted in 1 case. Contrast enhancement was noted in all cases in non necrotic areas which was moderate to intense.

Butler AR, Horri SC et al., in their study showed that that contrast enhancement of viable tumour including the peripheral rim and the intratumoral solid portions is nearly universal in glioblastomas<sup>22</sup>. Our study also revealed the same feature.

Out of 17 cases of glioblastoma multiforme, 15 cases were diagnosed as glioblastoma multiforme and 2 cases were diagnosed as anaplastic astrocytoma. So, the sensitivity is 88.2% in diagnosing GBM.

## **OLIGODENDROGLIOMA:**

Incidence of oligodendroglioma in our study is 2%.

Both the cases were hyperdense on plain CT with dense calcification and mild contrast enhancement and oedema. On MRI both the lesions were hetero intense on T1WI and T2 WI due to calcification. The diagnostic accuracy of oligodendroglioma in our study is 100%.

## **MENINGIOMAS:**

They are the most common nonglial primary brain tumour. Most are homogeniously hyperdense and densely enhances on contrast administration. According to Aronove et al ., in 1978 CT detects 85% and 95 % of cases in plain and contrast enhanced CT respectively.

Incidence of meningiomas in our study was 13.7% of primary brain tumours.

Male: female ratio 0.3 : 1 showing female predominance.

Peak age of incidence--5<sup>th</sup> and 6<sup>th</sup> decade.

### ***Distribution of meningioma in our study :***

Falx and convexity --7 cases (64%)

Supra sellar -- 2 cases

CP angle -- 2 cases

Naidich TP et al in 1990 in their study showed that the parasagittal region and the cerebral convexity are the common sites accounting for

nearly half of all meningiomas<sup>23</sup>. This same distribution pattern was seen in our study.

On plain CT 10 cases were homogenously hyperdense and one was isodense. Calcification noted in three cases 27.2 % and in CECT dense homogenous enhancement noted in all the cases. Dural tail was noted in 4 cases (36.3%).

Out of 11 cases of meningioma, correct diagnosis was made out in 10 cases, one was diagnosed radiologically as schwannoma which histologically turned out as meningioma. On MRI T2 WI most meningiomas appeared as iso to hypointense to the gray matter. Two cases appeared as hyperintense on T2WI which were meningothelial type of meningiomas on HPE. This is comparable with the study of Kaplan RD , Drayer BP et al., in year 1992 and Zee CS, Chin T et al in 1992 in which meningiomas with T<sub>2</sub> hyperintensity are of meningothelial type<sup>24,25,26</sup>.

#### **CIRCUMSCRIBED ASTROCYTOMA:**

All the cases in our study were pilocytic astrocytomas, two were supratentorial and two were infratentorial in location. All showed large cystic component and a mural nodule. And two cases showed calcification of the mural nodule. All cases showed mural nodule enhancement as per the following study.

Luh GY, Bird CR et al in 1999 showed that typically after intravenous administration of contrast agent dense homogenous enhancement of tumour nodule but not of the other walls of the cyst<sup>27</sup>.

### **MEDULLOBLASTOMA:**

In our study there were 7 cases of medulloblastoma out of 80 cases of primary brain tumours. The incidence was 8.7%. Most appeared hyperdense on plain CT and showed moderate contrast enhancement. They appeared hypointense on T1WI and hyperintense on T2WI and FLAIR. Three cases out of 7 showed diffusion restriction.

This is comparable to the study of Rodallec M, Colombat M et al., in 2004 in which 2 cases showed diffusion restriction suggestive of small cell histology<sup>28,29</sup>.

### **ACOUSTIC SCHWANNOMA:**

In our study, 5 cases were acoustic schwannomas which showed acute angulation with the petrous ridge. and the incidence was 6%. Most of them isodense to the cortex on CT and all showed contrast enhancement. Most were hypointense on T1WI and hyperintense on T2WI and FLAIR and showed no diffusion restriction.

### **TUMOURS OF SELLAR AND SUPRA SELLAR REGIONS:**

Pituitary adenomas are the common lesions in the sella accounting for 10 % of all primary neoplasms as reported by Russel and Rubinstein et al., in 1989. In our study of 80 cases 4 cases were pituitary macro adenomas

and three were craniopharyngiomas. All the pituitary macroadenomas enhanced well with contrast. And one showed carotid encasement. Most appeared hypointense on T1WI , slightly hyperintense on T2WI.

Incidence of craniopharyngioma in our study is 42% of sellar lesions. All occurred in children and all showed calcification. All showed heterointense signal in T1WI and T2WI due to cystic areas and calcification. All showed mild to moderate contrast enhancement (100%).

Johnsen DE Woodruff WW, Allen IS et al showed that of all the sellar region masses, craniopharyngiomas have the most heterogenous MR imaging spectrum<sup>30,31</sup>.

#### **ARACHNOID CYST:**

Two cases were arachnoid cyst one in posterior fossa and the another was in right middle cranial fossa. Both of them followed CSF signal intensity in all pulse sequences and showed no diffusion restriction.

#### **EPIDERMOID CYST:**

There were two cases of epidermoid cysts in our study. One was located in the left cerebello pontine angle and another was in middle cranial fossa. Both the lesions appeared hypodense on CT. On MRI they appeared hypointense on T1WI and hyperintense on T2WI. Both the lesions were not suppressed on FLAIR and they showed diffusion restriction. There was no contrast enhancement in both the cases<sup>32</sup>.

## **INTRAVENTRICULAR TUMOURS:**

There were 4 cases of intraventricular tumours in our study. The incidence was 5%. Two cases located in the body of the lateral ventricle and both were central neurocytomas. Both the lesions appeared heterodense with lobulated 'bubbly' appearance. One showed calcification. There was mild contrast enhancement. On MRI they appeared heterointense and showed attachment to the septum pellucidum and mild contrast enhancement.

One case was choroid plexus papilloma situated in the atrium of the right lateral ventricle which was lobulated and isodense on CT. On MRI the lesion appeared isointense on T1WI & T2WI. On contrast there was intense contrast enhancement. There was communicating hydrocephalus clearly demonstrated by both CT & MRI.

Shoemaker EI, Gado M et al study showed that intense slightly heterogenous enhancement following contrast administration is seen in virtually in all choroid plexus papillomas<sup>33</sup>.

Colloid cyst at the foramen of monro was well defined and hyperdense on plain CT. The lesion was hyperintense on T1WI and hypointense on T2WI. There was no contrast enhancement.

## **CONCLUSION**

Computed tomography and magnetic resonance imaging are excellent modalities in diagnosis of primary brain tumours especially in tumour location and extent.

In majority of the cases, it is possible to arrive at a specific diagnosis based on CT & MRI characteristics.

With these modalities we can also guide the neurosurgeons to the ideal site of biopsy and to support in deciding the nature of therapy.

## **ANNEXURE**

### **ABBREVIATION**

AA	–	Anaplastic Astrocytoma
CT	–	Computed Tomography
CECT	–	Contrast Enhanced Computed Tomography
Ca <sup>++</sup>	–	Calcification
Circ A	–	Circumscribed Astrocytoma
DWI	–	Diffusion Weighted Imaging
FLAIR	–	Fluid attenuation and Inversion Recovery Sequence
GBM	–	Glioblastoma multiforme
HPE	–	Histopathological examination
LA	–	Low Grade Astrocytoma
MRI	–	Magnetic Resonance Imaging
MRA	–	MR - Angiography
MRV	–	MR - Venography
MRS	–	Magnetic Resonance Spectroscopy
NECT	–	Nonenhanced Computed Tomography
ODG	–	Oligodendro Glioma
T <sub>1</sub> WI	–	T <sub>1</sub> weighted imaging
T <sub>2</sub> WI	–	T <sub>2</sub> weighted imaging
T <sub>1</sub> C+	–	T <sub>1</sub> contrast

## KEY TO THE MASTER CHART

### **Location:**

Rt- Right, Lt- left, CP- Cerebellopontine angle, TP- Temporo parietal region, PF- Posterior fossa,

### **Margins:**

WD- well defined, MD- Moderately defined, ID- ill defined

### **Density:**

Hypo – Hypodensity , Hyper – Hyperdensity, Het- heterodensity

ISO- Isodensity

### **Cont – Contrast**

+ - Mild enhancement, ++ - Moderate enhancement,

+++ - Intense enhancement

### **T1,T2, FLAIR :**

Hypo – Hypointensity, Hyper – Hyperintensity, Het- Heterointensity, Iso - isointensity.

**Diff** – Diffusion weighted imaging

### **Radiological diagnosis:**

LA - Low grade astrocytoma

AA - Anaplastic astrocytoma

Astro - Astrocytoma

GBM - Glioblastoma Multiforme

Pit - Pituitary

ODG - Oligodendroglioma

DAG - Diffuse Astrocytoma Grade
